## **Supplemental Methods**

### **Single cell cDNA and library preparation.**

Cell suspensions from skin were obtained as previously described (1). Briefly, skin biopsies were minced and digested enzymatically (Whole Dissociation Skin Kit, Miltenyi Biotec) for 2 hours at 37°C and further dispersed using the Miltenyi gentle MACS Octo Dissociator. A 3mm skin biopsy from each donor yielded 3,016-5,332 cells from tumor samples and 1,138-3,953 cells from HC skin. Experimental procedures followed established techniques (1) using the Chromium Single Cell 5' Library V1 kit (10x Genomics) and the Chromium Single Cell 3' Library V2 kit (10x Genomics). Cell suspensions were separated by the Chromium System (10X Genomics) (1-3) into mini-reaction "partitions" or GEMs formed by oil micro-droplets, each containing a gel bead and a cell. A 1000-fold excess of partitions compared to cells assured that most partitions/GEMs had only one cell per GEM. Gel beads contained an oligonucleotide scaffold composed of an oligo-dT section for priming reverse transcription, and barcodes for each cell (10X Genomics) and each transcript (unique molecular identifier, UMI), as described (4). 7,000 cells were loaded into the instrument to obtain data on ~4,000 cells with a rate of ~3.1% of partitions showing more than one cell/partition. The following steps were all performed using reagents and protocols developed by 10X Genomics. Following GEM formation, the emulsions were transferred from the Chromium chip to a PCR cycler for cDNA synthesis. The emulsion was then broken using a recovery agent, and following Dynabead and SPRI clean up, cDNAs were amplified by PCR (C1000, Bio-Rad). cDNAs were sheared enzymatically into lengths of ~200bp. The libraries were quantified using the KAPA Library Quantification Kit (Illumina), and further characterized for cDNA length by bioanalyzer using a High Sensitivity DNA kit.

### **RNA sequencing.**

RNA-seq was performed on each sample by the UPMC Genome Center (<https://upmcgenomecenter.com/research-offerings/>) using the NovaSeq 6000 sequencing system (Illumina). Genes detected (6,000 genes/cell) had a plateau at about 200,000 reads/cell (10X Genomics, white paper). We obtained ~200 million reads/sample (NovaSeq, Illumina) through the UPMC Genome Center, Sequencing Facility.

## **Data Analysis.**

Chromium scRNA-seq data produced by the 10X Chromium Platform were processed to generate sample-specific fastq files. Processed reads were then examined by quality metrics, mapped to a reference human genome using RNA-seq aligner STAR and assigned to individual cells of origin according to the cell specific barcodes, using the Cell Ranger pipeline (10X Genomics). To ensure that PCR amplified transcripts were counted only once, only single UMIs were counted for gene expression level (5). In this way, cell x gene UMI counting matrices were generated for downstream analyses. SoupX (6) was used to remove cell free mRNA contamination from each sample before analyzing with Seurat. The default parameters were used to calculate the contamination fraction as per reference. The corrected matrix was loaded into Seurat for further analysis. Seurat, an R package developed for single-cell analysis (7-11), was used to identify distinct cell populations and visualize cell clusters in graphs as in (2). Specifically, the UMI matrix was filtered such that only cells expressing at least 200 genes were utilized in downstream analysis. Samples were filtered for percentage of mitochondrial gene content under 25% and unwanted sources of variation were regressed out of the data by constructing linear models to predict gene expression based on the number of UMIs per cell as well as the percentage of mitochondrial gene content. Reciprocal PCA (RPCA) was utilized to integrate samples for batch correction analysis based on chemistry. Each set of samples was analyzed to find the top 2,000 highly variable genes and run principal component analysis (PCA) per chemistry. Integration anchors were then found for each group to combine the chemistries without batch effects. Cells were clustered using Seurat (Louvain clustering) (7). The resultant clusters were then visualized using a t-distributed stochastic neighbor embedding (t-SNE) projection plot (12). For cell-type identification, we used the “FindAllMarkers” function in Seurat, which uses the Wilcoxon rank sum test to show differential genes with a minimum percentage of cells of 25% per cluster, log-fold change  $>0.25$ , and p-value  $< 0.05$  for significance. For gene differential tests throughout the analysis, we used the “FindMarkers” function in Seurat, which uses the Wilcoxon rank sum test to show differential genes with a minimum percentage of cells of 10% per identity requested, log-fold change  $>0.1$ , and p-value  $< 0.05$  for significance (9-11). Harmony (13) was used to compare batch analysis tools.

## **Dataset integration**

Inter-dataset integration was performed using Reciprocal PCA (RPCA) in Seurat for batch correction analysis based on chemistry. Cell-gene unique molecular identifier counting matrices generated were analyzed using Seurat to identify distinct cell populations using Louvain clustering (7-11).

## **Connectome**

Ligand-receptor interactions were analyzed using Connectome v1.0.0. FANTOM5 ligand-receptor data was used for mapping. Ligand-receptor interactions were filtered for min percentage 10% within cell types, p-value <0.05, and z-scores over 0 to remove negative source/sink values for significance. CircosPlots were used to show up to 10 top significant interactions between individual cell types (14).

## **Identification of the malignant tumor clonotype**

We identified the malignant expanded clonotypes in MF samples (MF17, MF18, MF21, MF24) in a previous study (Gaydosik, A et al, 2022 Clin Cancer Res.). Briefly, we employed recent advances in scRNAseq methods that allow high resolution profiling of the T-cell immune repertoire simultaneously with gene expression, thus allowing the transcriptional profiles of expanded clonotypes to be assessed. With this approach, we showed that several non-overlapping clonotypes are expanded in the skin, including a more abundant dominant clonotype as well as additional less abundant minor clones. The distinction between malignant and benign clones is based on the gene expression and pathway upregulation by individual clones. The distinct gene expression and enrichment for specific oncogenic pathways previously reported by other human cancer studies clearly indicated the malignant nature of some clones while other clones present a transcriptional profile resembling benign reactive T cells.

## **Data availability**

All scRNA-seq data generated in this study have been deposited in the Gene Expression Omnibus database under accession numbers: GSE206123 and GSE182861. The AD and PS datasets analyzed in this study is available in the GEO database under the accession numbers: GSE153760 and GSE151177.

## **Pathway analysis**

The differential gene lists were filtered for p-value <0.05 for significance and then run in Ingenuity Pathway Analysis (IPA, Qiagen) for significant up-regulated pathways. Pathways were selected by enrichment scores (-log p-values) and absolute z-scores over 2 (15).

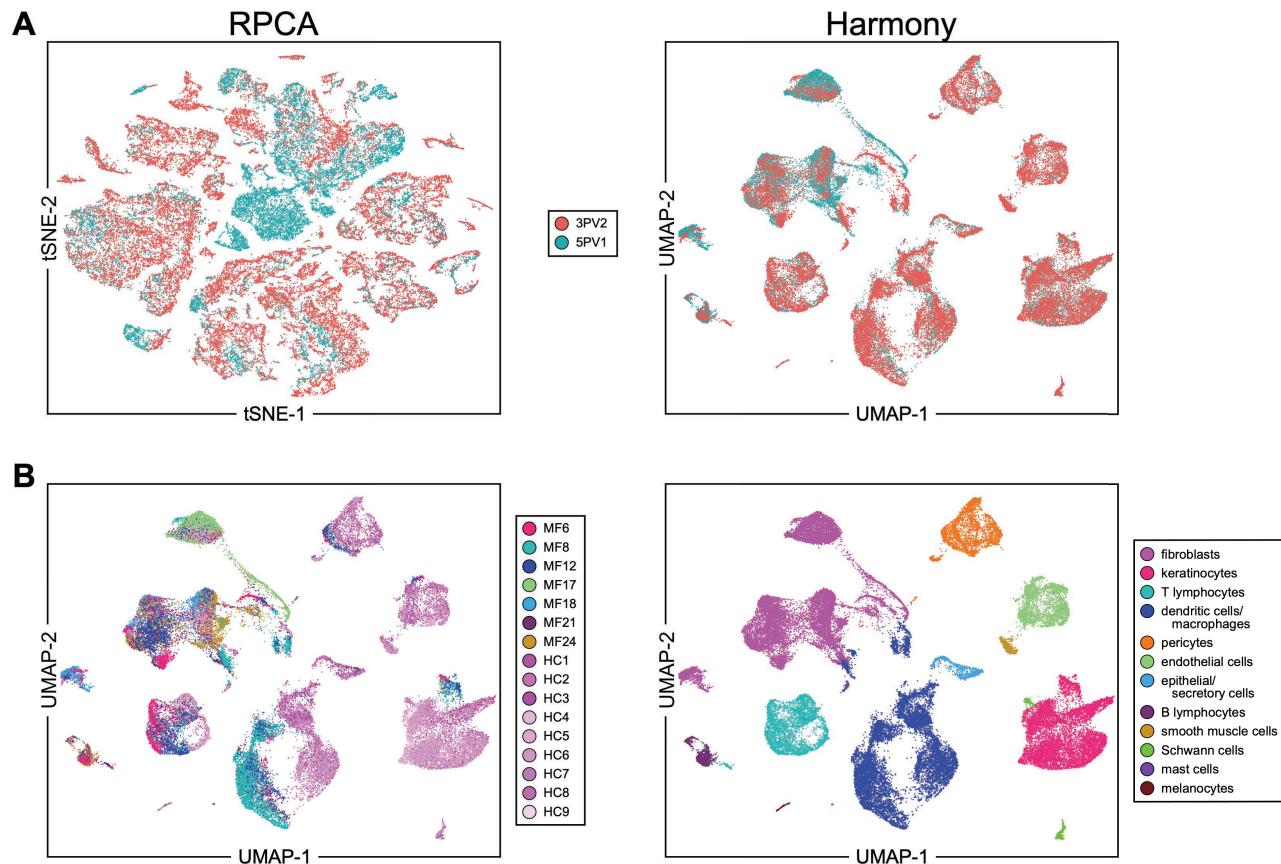

## **Multicolor immunohistochemistry**

Multi-color staining was performed on formalin-fixed, paraffin-embedded skin samples using the tyramide signal amplification kit (ThermoFisher) as previously described (1). The antibodies employed in these experiments are reported in Table S7. Confocal images were captured on an Olympus Fluoview 1000 confocal microscope using an oil immersion 100X objective.

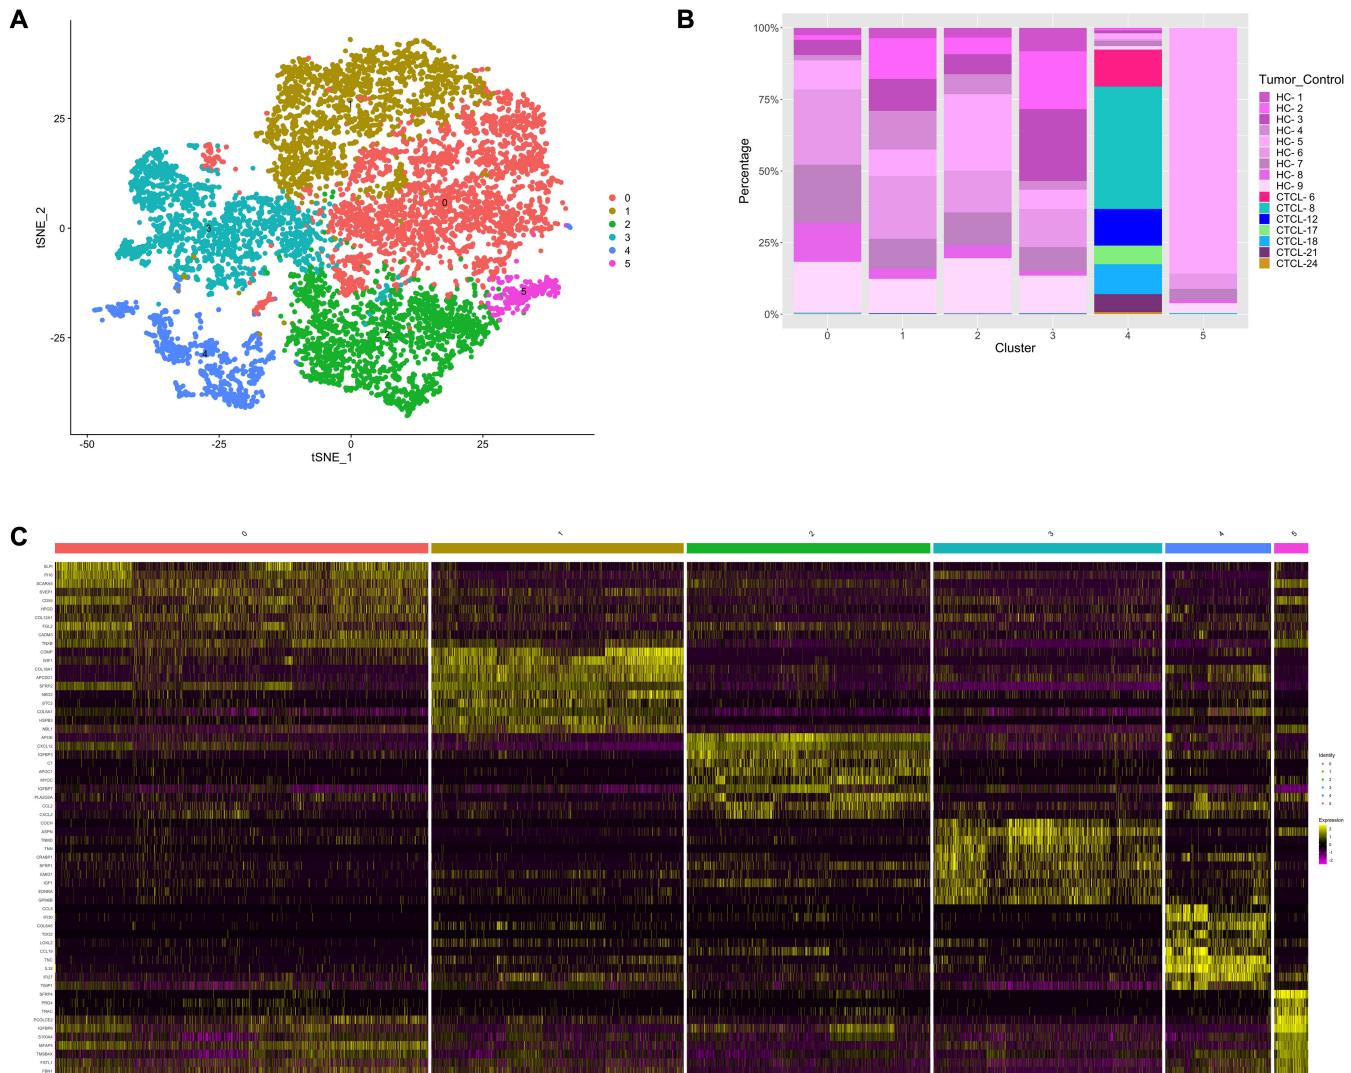

**Figure S1. Batch correlation analysis comparison by Harmony (13).** **(A)** Transcriptomes of 51,468 cells including all cell-types from nine healthy controls (HC) (24,322 cells) and seven advanced MF (27,146 cells) skin biopsies clustered using Reciprocal PCA (RPCA) and Harmony, respectively. Chemistry differences were corrected for in two-dimensional t-SNE and UMAP, respectively. **(B)** UMAP of all samples IDs to verify clustering exhibits no batch effects as no individual samples create own clusters (left panel). UMAP of all cell types using Harmony to verify there are no batch effects as all samples overlap per cell type in this UMAP as we have shown in Seurat's clustering (left panel). UMAP shows similar clustering as Seurat in separating out unique cell types (right panel).

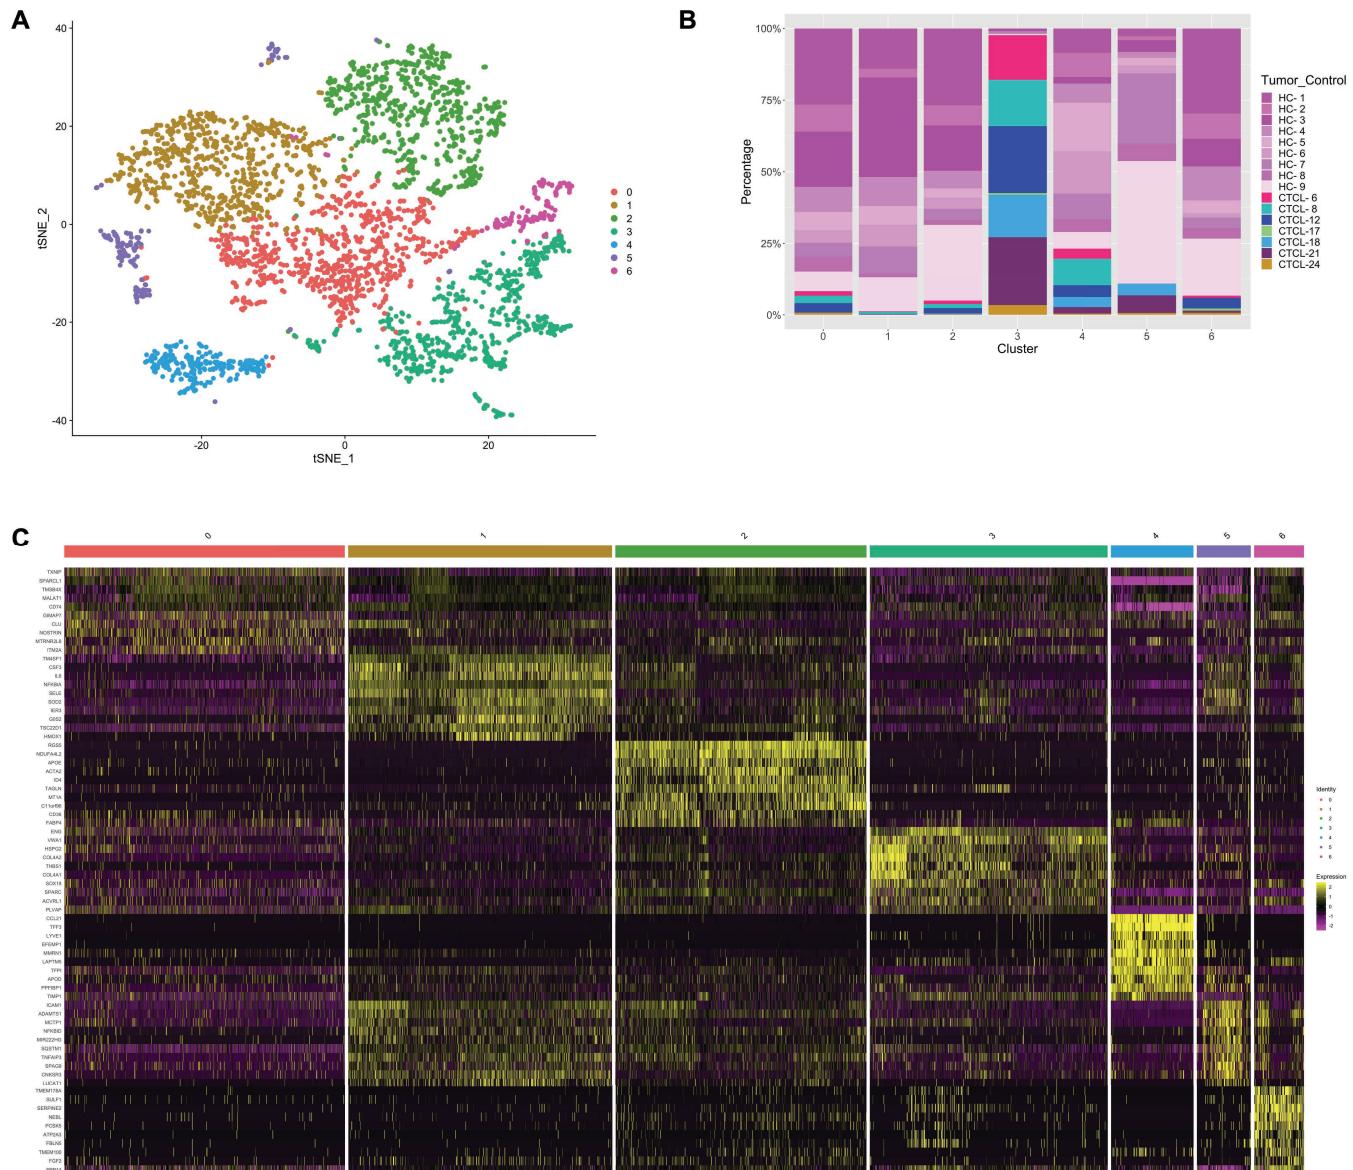

**Figure S2.** Dot-plot showing the proportion of cells and the scaled average gene expression of a panel of known markers for multiple cell types (1, 16-18) from all MF and HC sample combined (Figure 1, main text). Gene differential tests are described in the Methods. Briefly, we used the “FindAllMarkers” function of Seurat, which uses the Wilcoxon rank sum test to show differential genes with a minimum percentage of cells of 25% per cluster, log-fold change >0.25, and p-value < 0.05 for significance (9, 10).

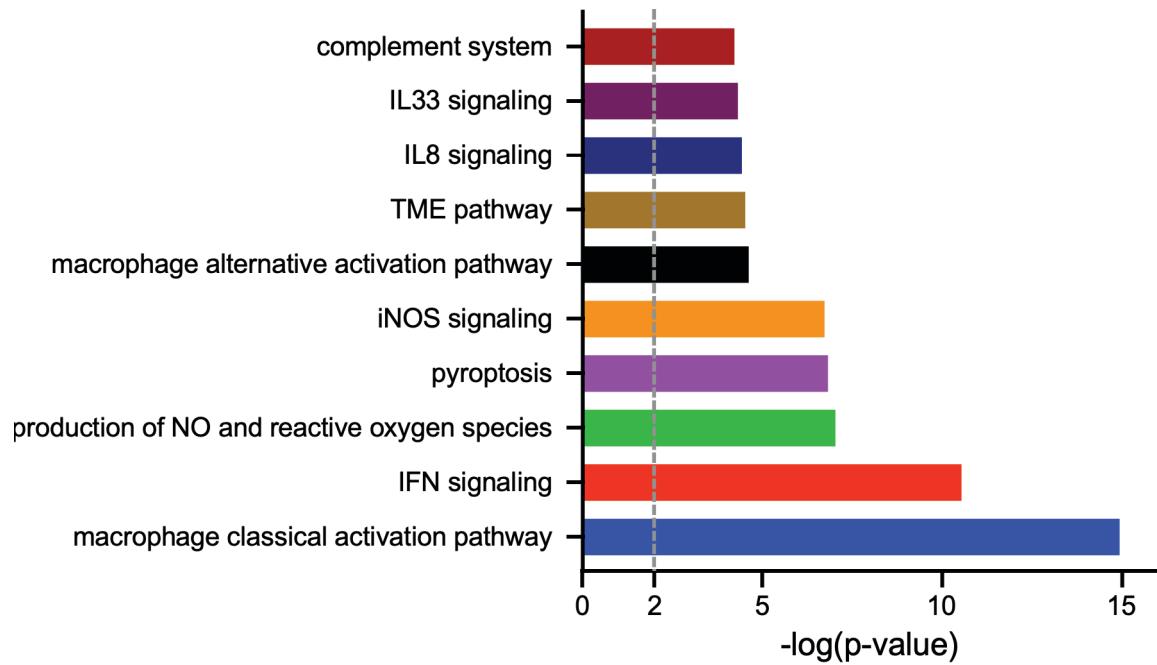

**Figure S3.** Myeloid-cell transcriptome in the cutaneous microenvironment of HC and MF samples. **(A)** Transcriptomes of 4425 AIF1<sup>+</sup> cells (1,730 from HC and 3,295 from MF skin samples) revealed 9 discrete Louvain clusters using Seurat (7, 8) (see main text Figure 2). Heatmap showing a selection of the most highly significant DE genes in each of these clusters (n=10). Cluster numbers are indicated at the top. Each column represents a cell. **(B)** The differential gene lists were filtered by p-value <0.05 for significance and then run in Ingenuity Pathway Analysis (IPA, Qiagen) (15) for significant up-regulated pathways. Highly significant examples of distinct pathways activated by individual clusters are shown. Pathways are represented by enrichment scores (-log p-values) and selected by absolute z-scores over 2 (15).

**Figure S4.** **(A)** Transcriptomes of 9,533 COL1A1<sup>+</sup> cells (8,748 from HC and 785 from MF samples) revealed 6 discrete Louvain clusters using Seurat (18, 19). **(B)** Bar plot showing the proportion of cells from each MF or HC sample within individual clusters. **(C)** Heatmap showing examples of the most highly significant differentially expressed genes (n=10) for each cluster from (A). Cluster numbers are indicated at the top. Each column represents a cell. Differential tests were performed as described in Material and Methods.

**Figure S5.** **(A)** Transcriptomes of 3,319 VWF<sup>+</sup> cells (2,503 from HC and 816 from MF samples) revealed 7 discrete Louvain clusters using Seurat (18, 19). **(B)** Bar plot showing the proportion of cells from each MF or HC sample within individual clusters. **(C)** Heatmap showing examples of the most highly significant differentially expressed genes (n=10) for each cluster from (A). Cluster numbers are indicated at the top. Each column represents a cell. Differential tests were performed as described in Material and Methods.

**Figure S6.** Highly significant examples of upregulated pathways by MF versus AD and PS myeloid cells are shown (Ingenuity Pathway Analysis, Qiagen) (15). Pathways are represented by enrichment scores (-log p-values) and selected by absolute z-scores over 2.

**Table S1.** Demographic and clinical features of patients.

Patient ID Age/Sex	Presence of Nodal Disease (Y/N with full description)	Stage*	TBSA (%patch, %plaque, %tumor)*	Year of Diagnosis/ Study Biopsy Date	Treatment prior to biopsy	Treatment at time of biopsy
MF 17 76/F	PET-CTs in 3/2019 and 4/2019 showed multiple new areas of FDG avid lymphadenopathy and FDG avid skin thickening relative to PET-CT from 2016. **Table S2.** Histology features of samples used in scRNA-seq and imaged in Figure 1A.

Patient No.	Histology and Immunohistochemistry
MF17	The patient presented with a prior history of tumor stage MF. A prior peripheral blood flow analysis (December/2016) showed marked eosinophilia and a clonal TCR population. The patient has completed several courses of antibiotics. Several anatomical punch biopsies were taken for pathological and TCR rearrangement analyses, including soft tissue, right arm, right buttock, core (January-April 2019). The skin architecture presents parakeratosis, spongiosis as well as foci with lymphocytes in the epidermis and in the dermis admixed with eosinophils. Lymphocytes show loss of CD5 and CD7, skewed CD4 to CD8 ratio (greater than 5:1 approaching 10:1 range). CD30 expression in large malignant cells. The actual percent of CD30 positive staining is not more than 20% but overall a significant extent of the large cell infiltrate does express CD30. The lymphocytic infiltrate is positive for clonal TCR-beta gene rearrangement, consistent with a clonal lymphoid population in the sample. Pas stain fails to reveal fungal hyphae or basement membrane thickening. Pathological examination was consistent with tumor stage granulomatous MF with large cell transformation and CD30 positivity.
MF18	The patient presented with an extensive patch and plaque-like eruption with a large tumor that has biopsied. This punch biopsy shows an extensive tumefactive lymphomatous process involving the entire sampled thickness of the dermis. In addition, there is focal infiltration of the epidermis by atypical lymphocytes, whereby the epidermal response is a varied one, ranging from attenuation to hyperplasia. The dermal infiltrate is highly atypical. There is infiltration of the adventitial dermis of the eccrine coil by malignant lymphocytes. While there are some smaller lymphocytes in the background, the prevailing lymphoid populace is intermediate to larger sized lymphocytes many of which have a large, transformed morphology, more open chromatin, and conspicuous basophilic nucleoli. A positive TCR was detected on flow cytometry. Multiple atypical lymphocytes stained positively for Beta F1. We detected an extensive immunoreactivity of the infiltrate for CD2, CD3, and CD7, but loss of CD5. CD4 and CD8 demonstrate reactive CD8 T cells in the background with a number of the neoplastic cellular elements expressing CD4 as well as lymphocytes with a double negative CD4 and CD8 phenotype. There is focal staining for granzyme. Multiple neoplastic cells show granzyme positivity noted amidst the neoplastic cells in the superficial dermis. A similar pattern is observed for TIA. The malignant lymphocytes also show immunoreactivity for CD25; the staining is cytoplasmic and relatively deep but a number of the cells show some staining likely in the realm of 50%. A significant number of lymphocytes are negative for Foxp3, CD56, CD57, or PD-1, EBER, CD30. Pathology was consistent with advanced tumor stage mycosis fungoides with large cell transformation.
MF21	The patient presented with a history of mycosis fungoides with reported CD30+ large cell transformation and lymph node involvement. There is an extensive pan-dermal highly atypical lymphocytic infiltrate accompanied by many histiocytes including multinucleated giant cells. The dominant localization of the infiltrate is dermal, closely apposed to the epidermis with focal areas of epidermotropism. In these focal areas, the lymphocytes are a mixture of small, intermediate, and very atypical larger lymphoid forms. The infiltrate within the dermis is characterized by highly atypical large lymphocytes (15-20 micron) manifesting complex nuclear contours with conspicuous eosinophilic nucleolation. This highly atypical lymphoid population exhibits a coalescing multinodular and sheet-like growth throughout the dermis. There is a palisade of histiocytes around areas of fibrinoid necrobiotic change whereby the epicenter is a damaged vessel showing luminal

	<p>and mural fibrin deposition with attendant red cell extravasation. Phenotypic analysis of the lymphocytes indicate that they are alpha-beta subset as revealed by the degree of immunoreactivity for beta F1. The T-cell nature of this malignant process is highlighted by the positive CD2, CD3, and CD5 stains. The CD7 stain is minimally positive; similarly, the TIA stain is negative except for a few reactive CD8-positive cells that show TIA positivity. Granzyme is positive in small reactive CD8-positive T cells. There are many malignant cells that show a very strong nuclear signal for TOX (~ 20%). There is an extensive degree of immunoreactivity for ICOS corresponding with the large cell activated morphology that prevails in this tumor. In contradistinction, the PD-1 stain is minimally positive. The Ki-67 proliferation index in focal areas is in the 30-40% realm with an overall percentage in the 20-30% realm. Many of the malignant cells are highlighted by CD4, while the CD8 preparation shows only a few reactive CD8-positive T cells. The CD4-CD8 ratio is in excess of 10:1. There are a number of malignant lymphocytes, however, that are double-negative. Most of the tumor is negative for CD30 expression. The infiltrate is largely localized within the dermis with minimal epidermotropism. The malignant cells have a highly atypical morphology with 20-30 micron size range. The findings are consistent with tumor stage mycosis fungoides with extensive pan-dermal large cell malignant lymphoid infiltrate.</p>
<b>MF24</b>	<p>This patient presented with a history of tumor stage mycosis fungoides with concern for large cell transformation. The biopsy is significant for a nodular infiltrate of atypical lymphocytes that have open chromatin and frequent single-cell necrosis. Mitoses are also seen. The cells are large in size. Large cells occupy more than 80% of the atypical lymphocytic population. The lymphocytes are composed of CD3 positive T cells. Interestingly, the T cells actually appear to have partial loss of CD3 expression. The lymphocytes are diffusely immunopositive for CD5, and when CD3 is compared to CD5, there is at least 50% loss. The lymphocytes also show similar loss of CD2. The atypical lymphocytes show diffuse PD-1 expression, and they also show nuclear positivity for TOX. Ki-67 shows proliferation in the range of over 90%. A CD7 immunostain shows reduction in the range of 60%. The T cells are dominated by CD4 positive cells with an over 6:1 CD4-CD8 ratio. The T cells are also immunopositive for beta F1. A CD30 is only positive in less than 5% of the cells. The findings are consistent with tumor stage mycosis fungoides with CD30 negative large cell transformation.</p>
<b>MF6</b>	<p>An atypical lymphoid infiltrate with CD2, CD3, CD4 and CD5 immunostains mark the majority of the cells within the infiltrate. CD7 immunostain appears slightly down regulated. CD8 immunostain marks one third of cells within the infiltrate. CD79a and CD20 immunostain mark a very small minority of the cells in the infiltrate. There is a significant eccrinotropic and vasocentric component with evidence of vascular injury. The neoplastic lymphocytes are noncerebriform and are predominated by small and intermediate sized lymphocytes with a minor large cell component (&lt;30%) without evidence of CD30 and ALK1 positivity. CD56 immunostain is mostly negative. TCR gamma immunostain is negative. EBER is negative. T-cell receptor-beta gene rearrangement is positive for clonal TCR-beta gene rearrangement, consistent with a clonal lymphoid population in the sample. This represents a T-cell lymphoproliferative disorder/lymphoma.</p>
<b>MF8</b>	<p>The patient had tumor stage mycosis fungoides with concern for large cell transformation. The biopsy shows a very striking and exaggerated pattern of psoriasiform epidermal hyperplasia. The findings are diagnostic of a fully evolved plaque stage lesion of mycosis fungoides. There is a striking pattern of follicular involvement captured on A1 whereby there is infiltration of the hair follicle and adventitial dermis by neoplastic lymphocytes. There are a number of neoplastic larger lymphoid elements within the epidermis and around blood vessels although insufficient to warrant categorization as large cell transformation since these larger cellular elements are intimately admixed with smaller lymphocytes (&lt;25%). Nevertheless, they are discernible and in certain perivascular aggregates they are more numerous corresponding to</p>

	focal areas where the perivascular Ki-67 proliferation index is quite high (> 50%). Overall, the findings are compatible with plaque stage mycosis fungoides with follicular involvement and a subtle interstitial granulomatous component with supervening pustular and eczematous features. Phenotypic analysis indicates that the lymphocytes are primarily alpha-beta (beta-F1 <sup>+</sup> ). They are also extensively highlighted by CD3 and CD5 positivity, but with a significant decrease for CD2 and CD7 of approximately 80%. There is a strong nuclear signal for TOX amidst the neoplastic lymphocytes. The NFAT preparation shows a cytoplasmic staining pattern without significant nuclear staining. The proliferation index is variable. In some of the nodular lymphocytic foci (~50%). The CD30 stain highlights a few of the lymphocytes, mostly in the epidermis (<10%). In examining the CD4 and CD8 preparations it is apparent that the neoplastic cells are clearly of the CD4 subset, with the CD4 to CD8 ratio is in excess of 5:1. A diagnosis was rendered of mycosis fungoides with follicular involvement and early granulomatous features.
<b>MF12</b>	The patient presented with concern for tumor stage mycosis fungoides. The findings are those of an atypical epidermotropic lymphocytic infiltrate accompanied by a very extensive deeper seated tumefactive atypical lymphocytic infiltrate with a striking degree of granulomatous inflammation. Many of the lymphocytes have a cerebriform appearance and phenotypically the infiltrate is very abnormal showing a loss of CD2, CD5, beta-F1 and no staining for CD4 or CD8. Overall, the findings are compatible with an advanced tumor stage lesion of granulomatous mycosis fungoides. A significant part of the infiltrate in fact is histiocytic and is composed by smaller to intermediate size neoplastic T cells. There are scattered larger atypical cells of which a subset exhibit positivity for CD30 with an increased proliferation index in the 20-30% realm suggesting impending large cell transformation although not fulfilling the unequivocal criteria for large cell transformation. A diagnosis was rendered of tumor stage granulomatous mycosis fungoides with impending large cell transformation with focal CD30 positivity.

**Table S3.** Differentially expressed genes in keratinocytes that are common among the MF patient samples.
