

Supplement

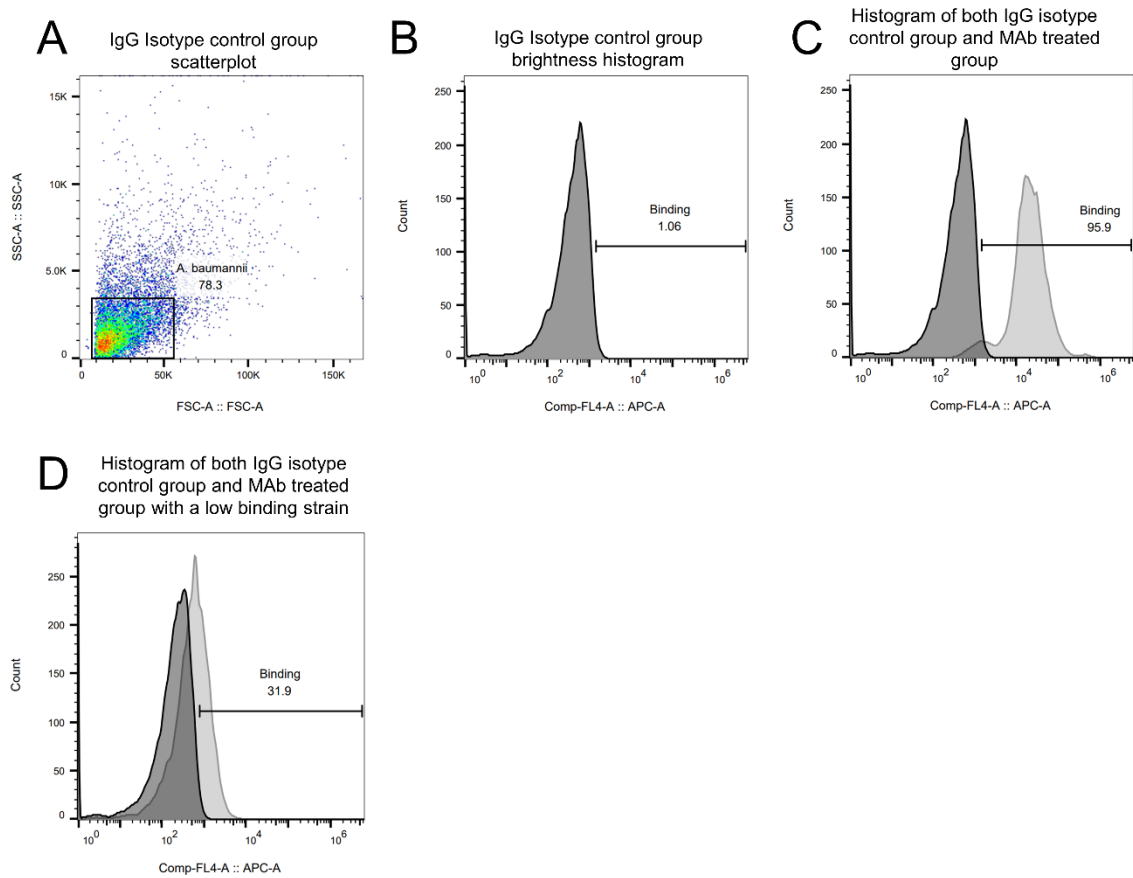

Figure S1. Bacterial flow cytometry gating strategy via Flowjo software and acquisition of percent binding. The flow cytometry events (10,000 events per sample) of the IgG isotype control group were first viewed on a forward scatter/side scatter plot, and a box gate was applied to select only the core events, eliminating any excessively large or granular events. This was done to prevent bacterial aggregates from contributing to the binding data (A). The events gated as in figure A were plotted as a histogram with the X axis indicating brightness on the flow cytometer's APC channel. A gate was produced to include all events brighter than the control group, as well as the brightest 1% of events within the control group (B). These gates were then applied to the MAb treatment group, and the percentage of events within the fluorescence gate were interpreted as percent binding (C). This process yielded different but comparable results for each isolate, and results in a wide range of binding reactions, with lower binding strains having heavy overlap between the control and MAb treated histograms, resulting in a lower percent binding (D). Subtle variations in the background fluorescence of the control group between strains used in figures B/C and D necessitate normalizing the results using a control group for each strain individually.

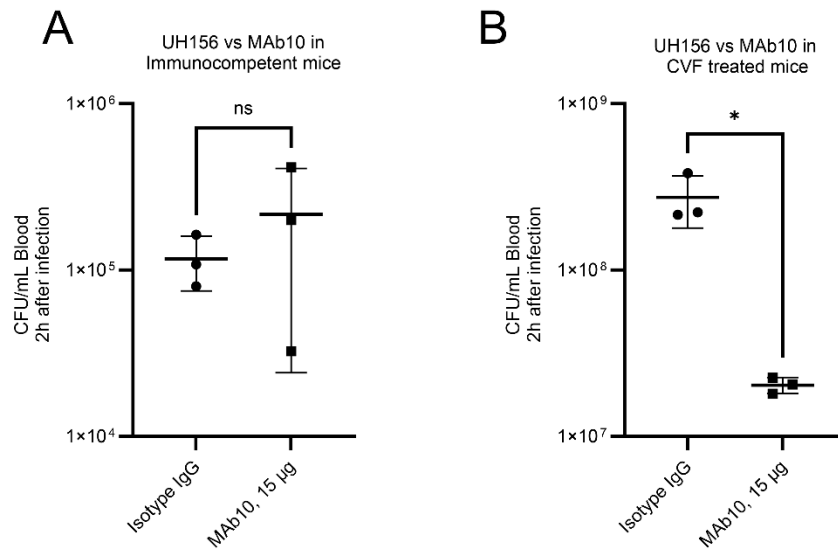

Figure S2. Explanation of Immunosuppressive regimen. Some *A. baumannii* strains were incapable of producing lethal infection, or even maintaining a significant enough presence in the bloodstream following infection to accurately assay the effects of MAb treatment. (A) Immunocompetent Mice (n=3/group) given 3.75e8 CFU of strain UH156 cleared the infection so efficiently that there was no difference in blood CFU between the control and MAb10 treated groups. However, mice given the same infective dose following cobra venom factor treatment to eliminate complement were unable to clear the infection with this same avirulent strain without MAb10 treatment. We do not anticipate that the immunosuppressive regimen has any impact on MAb efficacy beyond enabling these sublethal strains to be used in our infection model, given that we have previously established MAb efficacy in mice with both complement and neutrophil depletions (19-21).

Table S1. Flow cytometry comparison of humanized and murine MAb10. Percent binding of various *A. baumannii* isolates (n=30) with either humanized or murine MAb10 were compared. Assays were conducted identically. The fourth column shows the differential between murine and humanized MAb10 binding of each strain (calculated as murine MAb10 % binding – humanized MAb10 % binding). Strains with >10% difference between murine and humanized MAb10 are shown in grey.

MAB/Strain	Coefficient of Variation	Range	Variance

Table S2. Statistics of the consistency analysis of single-step flow cytometry as in Figure 5c. Coefficient of variation, variance, and range of all MAb/Strain combos assayed in the assessment of inter-assay consistency of the single-step flow cytometry assay are shown. Coefficient of variation is inflated by the low binding values of strains not bound, or weakly bound by our MAbs.

Strain	10 µg/mL MAb10	5 µg/mL MAb10	1 µg/mL MAb10	0 µg/mL MAb10
MRSN-17493	100	100	86.3	1.03
MRSN-1196	92.1	94.2	10.1	1.29
MRSN-7521	99.9	95.6	36.2	1.04
UH351	97.8	65.8	15.5	1.19
UH156	100	100	99	0.22

Table S3. MAb concentration titration analysis of single-step flow cytometry. Five *A. baumannii* strains were assayed for binding via the single-step flow cytometry method using 10, 5, 1 or 0 µg/mL MAb10, with a standard 2 µg/mL of secondary antibody. Titrating the MAb10 concentration had different effects on different strains, so the 10 µg/mL dose was used to maintain consistency.
